A margin is a statistic based on a  
fitted model in which some of or all  
the. margins— Marginal means,

predictive margins, and marginal effects 9. covariates are fixed.

Marginal effects are changes in the response for change in a covariate, which can be reported as a derivative, elasticity, or semielasticity.

Margins are statistics calculated from  
predictions of a previously fit model  
at fixed values of some covariates

and averaging or otherwise integrating over the remaining covariates. The margins command estimates margins of responses for specified values of covariates and presents the results as a table.

The first margin, 0.13, is the average probability of a positive outcome, treating everyone as if they were male. The second margin, 0.19, is the average probability of a positive outcome, treating everyone as if they were female. We can compare

The margins command can very easily tell you the mean effect: margins,

dydx(weight) What margins does here is take the numerical derivative of the expected price with respect to weight for each car, and then calculates the mean. In doing so, margins looks at the actual data. Thus it considers the effect of changing the Honda Civic's weight from 1,760

Using Margins for Predicted Probabilities. The margins command (introduced in Stata 11) is very versatile with numerous options. This page provides information on using the margins command to obtain predicted probabilities. Let ' s get

margins computes so-called margins of responses. `[_margin]` is a statistic computed from predictions from a model while manipulating the values of the covariates. `[_conditional margin]`: a prediction from a model where all covariates are set to `ref` values. `[_predictive margin]`: if some
